Abstract
The rise of Industry 4.0 technologies like artificial intelligence, IIoT, Big Data and robotics prompted China to integrate these technologies in its industrial sector. China undertook several initiatives like 'Made in China 2025', 'New Quality Productive Forces' strategy and the 'AI Plus' initiative to modernize its manufacturing sector into a smart manufacturing power. China's central government placed special emphasis on R&D to ensure a high-tech innovation-led growth. A close coordination between the central and municipal governments, as well as public-private cooperation, resulted in a palpable transformation of China's manufacturing sector. The emergence of new Chinese manufacturing giants, including BYD and CATL, surpassed their global competitors and strengthened China's grip on global value chains (GVCs). The elevation of Chinese manufacturing prowess created significant ripple effects in the global political and economic landscape, leading to protectionist policies by Western governments, especially the United States. The ensuing tariff war by the Trump administration, as well as the rare earth mineral war and semiconductor and chip war, demonstrates the global implications of the transformation of China's manufacturing sector.

INTRODUCTION

The phenomenon of the Industrial Revolution passed through several stages of evolution since the 18th century. The 1st Industrial Revolution was based on the steam engine and mechanical production, the 2nd Industrial Revolution was signified by assembly lines and mass production and the 3rd Industrial Revolution witnessed the incorporation of electronics and automation into the production process. The concept of the 4th Industrial Revolution, also known as Industry 4.0, was introduced by the German government in the early 2010s and was based on the concepts of cyber-physical systems supported by artificial intelligence, Internet of Things, cloud computing and robotics. The idea was swiftly adopted by other countries, including China, which aimed to revolutionize its industrial sector under the 'Made in China 2025'. This strategy highlighted China's plans to incorporate advanced cutting-edge technologies into its industrial sector and transform it into a smart manufacturing power. This strategy was carried forward by the New Quality Productive Forces strategy introduced in 2023 and the AI Plus initiative of 2024. The presence of this multitude of strategies raises several questions, including: How effective are China's policy documents regarding technology integration into China's manufacturing sector? How has China's manufacturing sector been transformed by the incorporation of Industry 4.0

Volume 4 • Issue 5 • September 2026

technologies? What are the global implications of the transformation of China's manufacturing sector? The paper delves into these queries to analyze how China became a smart manufacturing power and solidified its grip on the global value chains (GVCs) through centralized planning and execution at the municipal level of the integration of Industry 4.0 technologies in the industrial sector. The implications of this transformation at the global level are also discussed comprehensively, as China's rising industrial and supply chain domination had a significant impact on the global political and economic landscape. Qualitative research methodology is applied in the article and case studies of various Chinese firms are analyzed to understand the application of advanced cutting-edge technologies in Chinese industries. Through this approach, the transformation of China's manufacturing sector is explained and interlinked with the changes in global political and economic dynamics.

Fourth Industrial Revolution (Industry 4.0)

The concept of the fourth industrial revolution was introduced by the German government in the early 2010s as Industry 4.0. The idea was swiftly adopted by other countries, including the US, UK, Japan, Italy and China. The idea of the 4th industrial revolution is based on the integration of advanced cutting-edge modern technologies into the industrial process in order to boost productivity. The biggest component of Industry 4.0 is the cyber-physical systems, which refer to the assimilation of artificial intelligence-based systems, storage systems and production systems, as their working is synchronized for a higher efficiency. This allows for the integration of real-world machines and virtual cyber systems. The IT systems are linked with mechanical and electronic components, which are connected to the online networks. This allows the machines to interconnect with each other through the virtual domain. This mechanism of cyber-physical systems relies on the Internet of Things (IoT), allowing physical systems and computer algorithms to be integrated. The Internet of Things (IoT) consists of a number of digital technologies, such as sensors, communication modules, and different software programs, that work together to digitally link tangible physical components with the digital world and provide continuous and easily accessible data about those systems. Given the enormity of the data, the phenomenon of Cloud Computing allows the data to be stored over the internet.

The major technologies associated with the 4th industrial revolution include Artificial Intelligence, Cyber Physical Systems, Cloud Computing, Robotics, Internet of Things and Big Data. These technologies result in a streamlined integration of cyber systems with physical systems. Through this integration, the entire production process has been revolutionized as the entire production process is now monitored virtually and the machines communicate with each other via cyber systems. The margin of human error has been substantially reduced while productivity has significantly increased. The modern industries do not rely on physical assembly lines and manual labor; rather, robotics has taken charge of the majority of operations, converting the industries into smart industries.

Made in China 2025

Made in China 2025, launched in 2015, refers to China's ten-year plan to integrate advanced cutting technologies into its industrial sector and become a global smart manufacturing power. The strategy intended to incorporate the tenets of the 4th industrial revolution into China's manufacturing sector. It highlighted several key sectors, including artificial intelligence, robotics, aerospace, advanced IT, automated machine tools and new energy vehicles. This strategy was spearheaded by the central government and resources were to be allocated for the successful implementation of the strategy. This would reduce China's reliance on foreign technology and would enhance China's self-reliance in scientific innovation and industrial upgradation by employing advanced cutting-edge technologies.

As part of the strategy, industrial R&D became a major component of China's new industrial planning. Additionally, the green economy was also given substantial consideration as smart

JOURNAL FOR SOCIAL SCIENCE STUDIES
An International Peer-Reviewed Open Access Journal
ISSN (Online): 3006-2071 | ISSN (Print): 3006-2063
Volume 4 • Issue 5 • September 2026

manufacturing was to be ensured through sustainable means. Aviation, including drone technology, high-tech ships and advanced rail transportation equipment was also included in the Made in China 2025 strategy as they were considered vital for the logistics side of smart manufacturing. These high-tech innovations would boost productivity, strengthen China's grip on the supply chain and enhance China's global stature as a smart manufacturing power.

New Quality Productive Forces Strategy

President Xi introduced the New Quality Productive Forces concept in September 2023 as the next chapter in China's industrial growth and manufacturing prowess. This strategy was conceived as the successor of the Made in China 2025 doctrine and greatly emphasized the integration of new technologies like quantum, biotechnology, 6G and artificial intelligence into China's industrial sector. This was intended to materialize the progress essential to compete with the global competitors in technology and production. The strategy aimed to upgrade China's economy from a traditional labor and production-intensive industry to an automated, advanced, cutting-edge technology-supported and innovation-led industry.

Innovation, spearheaded by futuristic technologies, was aimed at guiding China's industrial sector into the new age of growth and progress. The integration of new technologies and innovation would not only upgrade the existing industrial paraphernalia and their working modus operandi, thus increasing productivity, but also create new employment opportunities. The emphasis on innovation and investment in R&D was to be increased under the New Quality Productive Forces strategy while reducing the reliance on foreign investment. The new digital, automated and intelligent systems would ensure better qualitative growth in contrast to mere quantitative growth.

This integration of advanced cutting-edge futuristic technologies would axiomatically augment industrial productivity, indicating a sway from a traditional growth-led model to an innovation-led model of industry and economy. To ensure that, broad institutional reforms were also brought under consideration that would eliminate institutional and bureaucratic hurdles in the path of the strategy's materialization. The allocation of resources for the execution of the strategy would be ensured as part of the CCP's drive to ascertain smart manufacturing in China and strengthen its grip on global value chains. A major component of the strategy was its emphasis on sustainability and the green economy, as it holds vital importance in China's drive towards smart manufacturing.

'AI Plus' Initiative

The Chinese government introduced the AI Plus initiative in 2024 as an extension of the Made in China 2025 and New Quality Productive Forces strategy. The initiative, spearheaded by the central government and planned to be executed in collaboration with the local municipal governments, aimed at incorporating artificial intelligence across practically all spectrums of Chinese society. It is also closely aligned with the objectives of the 15th Five-Year Plan to be implemented between 2026 and 2030. The purpose of the initiative was to create an intelligent society that would utilize the full human capital, as the integration of artificial intelligence would spare humans from the trivial tasks and help boost productivity through extensive collaboration between humans and intelligent machines.

The AI Plus initiative aimed at integrating artificial intelligence across education, healthcare, governance, technology, cultural landscape and urban planning. Additionally, another major objective of the initiative is the comprehensive application of artificial intelligence in the economic sector, thus completely transforming the Chinese manufacturing sector into a smart manufacturing economy. The incorporation of AI in governance and urban planning would facilitate the smart manufacturing sector, as it would provide auxiliary support to China's rising exports and supply chains by streamlining the entire process and augmenting productivity and efficiency.

JOURNAL FOR SOCIAL SCIENCE STUDIES

Volume 4 • Issue 5 • September 2026

Concrete goals were set under the AI Plus initiative as part of the central government's drive to achieve an intelligent society and an intelligent economy. Dedicated efforts to enhance AI research would facilitate the R&D domain of the manufacturing sector, leading to a higher number of innovations and patents. As part of the initiative, a goal of 70% penetration rate of advanced intelligent terminals was set for 2027, which has to be raised to 90% by 2030. A completely intelligent society and economy is expected by 2035, which would surpass its global competitors in efficiency and productivity.

Transformation of China's Manufacturing Sector

China, since the introduction of the 'Made in China 2025' strategy in 2015, has taken concrete steps to incorporate Industry 4.0 technologies into its manufacturing sector. Strategies like 'Made in China 2025', 'New Quality Productive Forces' and 'AI Plus' initiative have been pushed as top-to-bottom strategies where the central government has introduced these initiatives to be enforced by the local municipal administrations. This state-led drive to integrate advanced cutting-edge technologies into the manufacturing sector has resulted in the actualization of smart manufacturing in China.

Artificial Intelligence has been at the forefront of these advanced cutting-edge technologies embedded into China's manufacturing paraphernalia. These AI-driven models are aimed at enhancing the production capacities of these industries, transforming them into smart industries. The AI-enabled systems enhance efficiency through automation as they catalyze the decision-making process, eliminating the risk of human error. As witnessed in the case of Midea, one of the biggest Chinese household electronics manufacturers, an integrated system of artificial intelligence and robotics performs the operations. The central artificial intelligence system oversees subsidiary AI systems, which control the robotics framework for different tasks. The manual laborers also wear AI glasses to interact with the AI systems and robotics, while the cameras on tools provide imagery for decision-making and streamlined functioning of operations. The AI systems interact with robots and the hardware, and the smart factories operate based on a smooth congruence between AI systems and the hardware. This reduces human involvement to a minimum whilst increasing efficiency and productivity.

The AI-based systems also play a crucial role in logistics, where they are used in warehouses and operated through sensors and cloud-based controls. The efficiency of the warehouses increases substantially as artificial intelligence helps with inventory, eliminating the issue of either shortage or overstocking. This reduces the reliance on manual labor and significantly enhances time management. It also helps with demand forecast as AI systems assess the previous patterns of consumer demand and can predict the inventory requirement. The AI-enabled logistics robots increase the operational capacity of warehouses and strengthen the supply chain capacity of the industries.

As observed in the case of Huawei, AI systems are fundamental in predictive maintenance as they spot preliminary indicators of equipment problems and failures, thus providing the opportunity to act beforehand, preventing major equipment failures and reducing the maintenance cost. Additionally, AI systems are also employed for quality assurance in the Chinese manufacturing sector. For accurate quality inspections, Mech-Mind Robotics combines AI and 3D vision. As a result, even the micro-defects are spotted and resolved. These AI systems are more efficient and swifter in assessing the quality of the products with the least margin of error. This introduces more accuracy and consistency to the manufacturing process, as the process is streamlined with the help of artificial intelligence. There are fewer recalls of the products, resulting in enhanced consumer confidence.

Lenovo's plant in the city of Hefei integrated an AI system into its manufacturing setup, specifically designed to receive and manage the scheduling of order and their efficient fulfillment. The R&D team used AI algorithms to assess five major categories that included 47 different aspects, including personnel, machinery, materials, procedures and the

JOURNAL FOR SOCIAL SCIENCE STUDIES

ISSN (Online): 3006-2071 | ISSN (Print): 3006-2063
Volume 4 • Issue 5 • September 2026

manufacturing setup. The team assessed innovative sorting techniques by diving into enormous databases pertaining to client orders, component suppliers, and product planning. Previously requiring hours of daily commitment from a specialized staff, its complete production schedule was drastically reduced to only 1.5 minutes. Production efficiency increased by an astounding 16% as a result of this change, and there was a notable 23 percent increase in personal computer manufacturing production and a 20 percent decrease in the backlog of orders.

The addition of humanoid robots, supported by artificial intelligence, into Chinese factories is resulting in enhanced productivity. The trivial tasks, previously assigned to manual labor, are now delegated to these humanoid robots, which perform them at a faster rate while reducing the time and cost. As a result, smart manufacturing is on a constant rise in China as labor-intensive processes are being replaced by intelligent automation systems that are more effective in performance. Robotics, a prominent Industry 4.0 technology, is a major component of the advancement of China's manufacturing sector, as companies like AgiBot and Unitree are leading the robotics manufacturing in China and paving the way for smart manufacturing in the Country.

Another feature of China's smart manufacturing is dark factories, referring to autonomous factories with minuscule to no human involvement. As evident from Xiaomi's dark factory in Changping, China, the entire factory is fully autonomous and operates entirely on Industry 4.0 technologies, including AI, big data, robotics and IIOT. Machines, supported by these technologies, oversee and operate all the procedures as every step of the production cycle is managed by robots and automated machinery, from sorting raw materials to final assembling and quality control. In addition to boosting productivity, this degree of automation reduces the possibility of human mistakes, guaranteeing sustained product quality. The factory's equipment has sophisticated AI and IIoT features, permitting it to work together and interact with each other. Real-time data exchange and decision-making are made possible by this interconnectedness, which optimizes production and minimizes downtime. Another component of Industry 4.0 technologies, i.e., big data, is also fundamental to smart manufacturing in China. Big data refers to enormous, intricate data collections that are too big for conventional data management solutions to handle. Big data may help businesses find new perspectives and come up with more informed choices when it is properly gathered, handled, and evaluated. China's biggest energy company, Sinopec, has incorporated Big Data applications into its operations and is witnessing advancements in predictive maintenance, workflow optimization and alarm management. The corporation intends to use the 4,050 TB of data that each of its forty facilities produces for decision-making and business assessment.

Industrial Internet of Things (IIoT) is another aspect of Industry 4.0, which has revolutionized China's manufacturing sector. The phenomenon of the Industrial Internet of Things (IIoT) refers to the incorporation and connection of wireless networks, big data, and analytical instruments with industrial and physical equipment. IIoT is growing in usage in China's manufacturing sector, as China has already built more than 2.57 billion IoT terminals as of 2024 and holds one-third of global IIoT connections. Chinese manufacturers like Alibaba & Tencent are gaining more insight into their business operations and the efficiency of their manufacturing lines with the help of IIoT, as it is fully integrated with their production lines and is essential for a more intelligent and sustainable production process. The Internet of Things (IoT) has been rapidly transforming conventional enterprises into more intelligent and sustainable ways of production by facilitating real-time data collaboration and AI-driven assessment.

Global Implications of China's Manufacturing Sector's Transformation

The successful implementation of the 'Made in China 2025' and the continuing operationalization of the 'new quality

Volume 4 • Issue 5 • September 2026

productive forces' strategy have resulted in the ascendance of the Chinese manufacturing sector on the global stage. Chinese cities have transformed into specialized clusters of economic zones facilitated by advanced cutting-edge technologies. Different industrial parks are dedicated to specific manufacturing sectors, becoming hubs for those manufacturing domains. These industrial parks, facilitated by Industry 4.0 technologies, including artificial intelligence and big data, among others, demonstrate a synchronized value chain as they specialize in the complete manufacturing process, from research and development (R&D) and design to manufacturing and logistics.

Chinese manufacturing leaders recognize the importance of innovation and ingenuity in the manufacturing sector as they strive to compete with global competitors. Chinese companies, across almost all manufacturing sectors, including the automobile industry, low-altitude economy, communications sector and clean energy sectors, maintain a special focus on R&D. A significant portion of their annual budgets is allocated for R&D. This is a major reason that Chinese manufacturers are outcompeting their global competitors as they not only focus on mass production, but also bring innovation to their products.

Additionally, the emphasis on R&D has led to a transition in China's manufacturing sector from a low-value-added to a high-value-added sector. This upward shift in the value chain is ascribed to the incorporation of advanced cutting-edge technologies stressed in 'Made in China 2025' and 'new quality productive forces' strategies. Due to the integration of these technologies, including robotics, big data, IIOT and artificial intelligence, China is no longer merely the world's largest factory, but an innovation hub. The number of patents held by China's technological and manufacturing sectors places the Country among the global innovation leaders. This status is reflected in China's rise in the global value chains (GVCs), as China leads the global export of high-tech manufacturing, including electric vehicles, robotics and aerospace components.

The incorporation of Industry 4.0 technologies in China's manufacturing sector led to the emergence of new manufacturing leaders in China that surpassed the global manufacturing giants. China's ascendence in the EV market, as symbolized by the successful rise of BYD, illustrates China's recently attained dominance in the global manufacturing sector. BYD's exports to Europe surpassed Tesla in 2025 as the former sold 150,000 units in Europe during the year's first quarter compared to the latter's 120,000 units during the same time. BYD's global sales amounted to 878,498 units from January to November 2025, demonstrating a 144% upsurge from the same period last year.

China's dominance in the field of lithium-ion batteries gives it a significant edge over other countries. By dominating the lithium-ion batteries' domain, China controls the global value chain of electric vehicles. China's Contemporary Amperex Technology Co., Limited (CATL) is the leading battery exporter in the world. This prominence of CATL manifests the reliance of not only global EV manufacturers but also the energy storage and aviation sectors on CATL's batteries, which validates China's lead in global value chains (GVCs). The palpable advancement in the manufacturing process and consolidation of GVCs resulted in China recording a trade surplus of over USD 1 trillion in 2025.

The strengthening of China's manufacturing sector and its firm grip over the GVCs also allows it to alleviate its reliance on foreign firms, as local manufacturing giants outperform the foreign players in China's domestic market. In the 1980s, when several new port cities, including Shenzhen, started transforming into industrial hubs, foreign investment was at the helm of this transition. However, China's industrial cities and its clusters of economic zones are now dominated by local manufacturing players, which reduces China's reliance on foreign investment as foreign firms face stern competition from Chinese manufacturers. The emergence of BYD as China's top EV seller, expected to surpass Tesla's global sales, demonstrates China's

JOURNAL FOR SOCIAL SCIENCE STUDIES
An International Peer-Reviewed Open Access Journal
ISSN (Online): 3006-2071 | ISSN (Print): 3006-2063
Volume 4 • Issue 5 • September 2026

manufacturers' dominance over foreign companies.

China's key manufacturing firms extended their footprint in other countries, solidifying their status as global value chain leaders. These Chinese firms have a network of production facilities and warehouses in other countries, as they form a deeply connected framework of value chains. Over 2000 overseas warehouses of Chinese companies demonstrate the reach of the Chinese manufacturing sector to its consumers across the continents. The addition of advanced technologies, e.g., automated sorting systems as well as unmanned delivery systems in the logistics component of the value chain, further augments China's manufacturing prowess, as Chinese products are delivered swiftly to its consumers.

The advancement of China's manufacturing sector and the rise of China in the global value chains (GVCs) had political repercussions, as it heightened the insecurity of the West, previously leading in manufacturing and supply chains. The political rhetoric of Western leaders started shifting against China as they accused China of violating the rules-based order and coercive economic policies. This rhetoric deliberately demonized China and presented China and its political and economic system in a negative pretext as the Western political leaders tried to protect their voter base. These political forces interlinked the rising inflation and reduced growth in their countries with China's manufacturing ingress into their countries.

The discursive vilification of China was aimed at the middle class of Western nations, especially the United States, where their deep economic and racial resentments were invoked and directed towards foreign elements. Mass migration was declared a threat to the racial supremacy of the native population as well as the employment opportunities of the middle class. Similarly, China's manufacturing prowess was also pushed as a reason for capital flight out of these countries into China, leading to reduced employment opportunities in those countries. US President Donald Trump openly articulated his apprehensions about China, calling for reduced trade with China to diminish China's economic strength and force companies to invest in the United States.

In order to undermine China's manufacturing capabilities and plummet Chinese exports, US President Donald Trump opted for protectionist policies and raised tariffs on China's exports to the United States. Instead of improving the investors' confidence, enhancing the bureaucratic and institutional modus operandi to facilitate investment, focusing on the human capital and building the clusters of special economic zones bolstered by Industry 4.0 technologies, President Donald Trump pursued the policy of economic coercion. The Trump administration accused the Chinese government of providing state support to Chinese enterprises, which affected the free-market dynamics and altered the level playing field in favor of Chinese firms.

This assertive posture of the American leadership resulted in a massive tariff war between the US and China as President Donald Trump attempted to coerce China into acceding to US demands through the enforcement of stringent tariff regimes. In just a few days into his presidency, President Donald Trump imposed 10% tariffs on Chinese goods entering the United States with a view to curtail Chinese exports and tilt the balance of trade towards the US. China, undeterred by Trump's coercion, imposed 15% levies on American coal and LNG, as well as 10% for crude oil and the automobile sector. As a result, Trump's 10% tariffs quickly spiked to 20% by the start of March, only to be countered by 10-15% Chinese tariffs on American agricultural products.

In response to Trump's 34% in early April, China imposed an equal reciprocal tariff on American imports. Within weeks, the Trump administration raised the tariffs to 84% and then 125%, again to be matched with equal Chinese reciprocal tariffs. This resulted in President Trump raising the tariffs to an exorbitant 145%, leading to speculations about a recession while severely impacting the global supply chain. The resultant Geneva talks in May eased the tensions as both countries reduced the tariffs by a significant percentage. A framework

ISSN (Online): 3006-2071 | ISSN (Print): 3006-2063
Volume 4 • Issue 5 • September 2026

deal was agreed upon during the London talks in June. The initial fentanyl-related 10% tariffs of February, 10% Liberation Day tariffs of April persisted, while 30% US tariffs on most Chinese goods also continued in practice.

The advancement of China's manufacturing sector also triggered a major clash over rare earth minerals between the US and China. Rare earth minerals refer to 17 elements that are crucial to the production of electric vehicles (EVs), medical equipment, oil refining, and other military applications such as missiles and radar systems. These rare earth metals are vital to the American defense industry as they are used in the US aviation, missile and radar systems, along with other defense equipment. China, which produces almost 69% of these rare earth minerals and has the capacity to refine 90% of these minerals, used them as a strategic leverage against the US in the ongoing trade war. In response to Trump's Liberation Day tariffs in April 2025, China restricted the export of several rare earth minerals to the US. After a negotiated ease, China imposed more stringent restrictions in October – later reversed – in response to Trump's continued tariff enforcement. This not only illustrated China's strategic use of its rare earth minerals but also its firm grip over the value chain of rare earth minerals essential for Western industries and the manufacturing sector.

The incorporation of Industry 4.0 technologies, which led to the rise of China's manufacturing sector, also led to a semiconductor and chip war between the US and China. Threatened by China's progress in the communications sector, Donald Trump, during his first tenure in the Oval Office, imposed wide restrictions on Huawei, precipitating the US assault on China's communications sector and chip domain. In October 2022, the Biden administration imposed a ban on the export of high-end microchips to China. These included AI chips comparable to or advanced than the Nvidia A100 chip, as they were considered essential to China's smart manufacturing, especially artificial intelligence-based programs and systems.

The Trump administration in 2025 continued attempting to undermine China's smart manufacturing system by holding the chips as leverage in the trade war. In August 2025, as part of negotiations over tariffs and rare earth minerals, the US government gave Nvidia the license to sell advanced AI H20 chips to China, and on 8th December, the sale of the most advanced chips, Nvidia H200, to China was permitted. This demonstrated that China's manufacturing prowess and its stern grip over the global value chains of the rare earth minerals compelled the US to relax its export ban on advanced semiconductor chips.

This multitude of non-military conflicts, including the tariff war, the rare earth mineral war and the semiconductor and chip war, demonstrates the American unease with the rising stature of China owing to its ascendance in the manufacturing sector due to state patronage of Chinese firms, focus on R&D, establishment of the clusters of special economic zones and an emphasis on human capital. The rising stature of China and its manufacturing acumen is resulting in a shift in global hierarchies, as China's strengthening manufacturing sector has a major role in hastening the global power shift from a unipolar to a multipolar system. China, which has already surpassed the US in global exports, recorded a trade surplus of above USD 1 trillion in 2025.

China continues to achieve newer milestones in technology every year and the integration of Industry 4.0 technologies into its manufacturing sector has allowed China to become a global leader in manufacturing, technology and supply chain. The world now looks towards China as it extends its footprint across continents through its Belt and Road Initiative (BRI), ascertaining regional connectivity and economic prosperity. The successful enforcement of the Made in China 2025 strategy and its continuation through the 'new quality productive forces' strategy are envisaged to continue transforming the global order as China moves leaps and bounds in the manufacturing sector by astutely integrating advanced cutting-edge technologies into its manufacturing sector.

Conclusion

The advent of advanced cutting-edge technologies like artificial intelligence, IoT, Big Data and robotics paved the way for cyber-physical systems, which revolutionized the industrial sector and laid the foundation of the 4th Industrial Revolution. The integration of these Industry 4.0 technologies in the industrial sector became a core focus for China, which introduced several initiatives, including 'Made in China 2025', 'New Quality Productive Forces' strategy and the 'AI Plus' initiative. Made in China 2025 highlighted ten key areas and outlined the strategies for the application of advanced technologies in order to modernize China's industrial sector and transform it into a smart manufacturing power. The New Quality Productive Forces strategy stressed the integration of new technologies like quantum, biotechnology, 6G and artificial intelligence into China's industrial sector, reorienting it into an innovation-led sector. The AI Plus initiative articulated the integration of artificial intelligence across the spectrum, at governance, education, technological, urban development and industrial sectors to ensure China's rise as a smart manufacturing power. The Chinese government diligently worked on these initiatives in close coordination with the local municipal governments and the private sector. Resource allocation for industrial R&D became a major focus, transforming China's manufacturing sector into a high-value innovation-led sector. New manufacturing front-runners emerged in the Chinese manufacturing sector that outcompeted their global competitors by bringing innovation to their products. BYD has become a flagship example of China's manufacturing prowess as the EV giant surpassed Tesla in global EV sales. The integration of robotics, IIoT and Big Data completely revolutionized the operations of Chinese industries and warehousing operations, thus strengthening China's grip on global supply chains. The rising stature of China's manufacturing sector also prompted insecurity among its competitors, especially the US, as it waged tariff war and semiconductor and chip war against China, though firmly retaliated in the rare earth metals domain, as well as through reciprocal Chinese tariffs. China's manufacturing sector's rise is linked with the Chinese aim of community with a shared future, and its Belt and Road Initiative aims to enhance the regional and global connectivity. China's focus on the integration of advanced cutting-edge technologies in its industrial sector and innovation-led growth is showing tangible outcomes. The global political and economic order is being palpably reshaped owing to China's rise in the manufacturing sector.
